i. An apparatus for automatically reducing noise from a work machine, comprising:

a memory device for storing desired noise levels for each location within the work site; and

2. The apparatus of claim 1, wherein the location determining device is a global positioning system.

the engine is limited to a first speed in the normal mode of operation,

the second speed is less than the first speed.

4. The apparatus of claim 1, further comprising:  
an engine driving a transmission input shaft; and

a transmission which selects a gear ratio, or ratio of the speed of an output shaft of the transmission to the speed of the input shaft of the transmission, wherein:

a first shift point between a first gear ratio and a second gear ratio is determined for the normal mode of operation,

a second shift point between a first gear ratio and a second gear ratio is determined for the reduced noise mode of operation, and

the second shift point occurs at a lower engine speed than the first shift point.

5. The apparatus of claim 1, wherein the desired noise level for each location within the work site varies with the time of day.

6. The apparatus of claim 5, wherein the desired noise level at night is less than the desired noise level during the day.

7. The apparatus of claim 1, wherein sound level meters are used to determine the desired sound level for each location.

8. The apparatus of claim 1, further comprising a central control center which transmits the desired noise level for each location to the memory device.

9. A method for automatically reducing noise from a work machine having a location determining device for determining the location of the work machine within a work site, a memory device for storing desired noise levels for each location within the work site, and a control unit, comprising the steps of:

determining the location of the work machine from the location determining device;
